

# Superhappiness: Charting the Future of Consciousness

An exploration of the arguments for and against radical mood-enrichment.

# Our Emotional World is Defined by the Hedonic Treadmill

Centuries of technological and socio-economic 'progress' haven't left us discernibly happier than our hunter-gatherer ancestors. Our emotional well-being consistently returns to a heritable 'set-point' despite life's highs and lows.

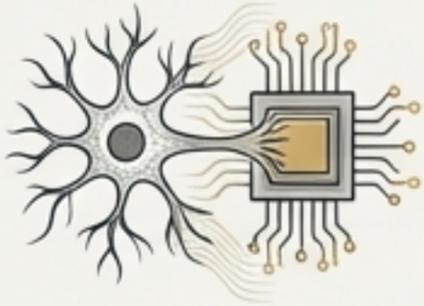

*But what lies beyond the boundaries of this map? Is happiness an absolute good, like intelligence or lifespan, that we should strive to enhance without limit?*

# Ten Navigational Challenges on the Journey to Enriched Consciousness

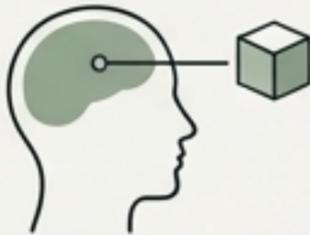

## The Foundations of the Idea

1. The Ethical Challenge

2. The Technical Challenge

3. The Experience Machine Challenge

## The Impact on the Self

4. The Inappropriate Responses Challenge

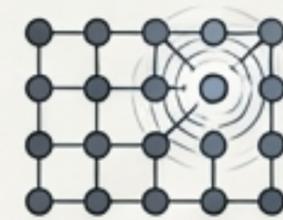

5. The Character-Sapping Challenge

6. The 'Stuck-in-a-Rut' Challenge

## The Impact on Society & The Species

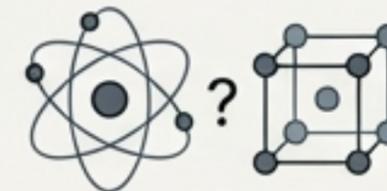

7. The Socially Disruptive Challenge

8. The Selection Pressure Challenge

9. The Risks-of-Haste Challenge

10. The Substrate (Carbon Chauvinism) Challenge

# Part 1: The Foundations of the Idea

## The Challenges

### 1. ETHICAL

Is debating posthuman bliss morally frivolous when billions of sentient beings still suffer? Shouldn't our sole focus be on abolishing suffering first?

### 2. TECHNICAL

Does it even make sense to speak of being "a thousand times happier"? Is well-being a definable, quantifiable biological category that can be indefinitely amplified?

## Possible Paths Forward

### RESPONSE (ETHICAL)

The relief of suffering carries greater moral weight. However, long-term planning isn't immoral. Transhuman goals like superlongevity or superintelligence will not increase long-run happiness *unless* we also recalibrate the hedonic treadmill. It is arbitrary to "freeze" this recalibration at the bare minimum needed to abolish suffering.

### RESPONSE (TECHNICAL)

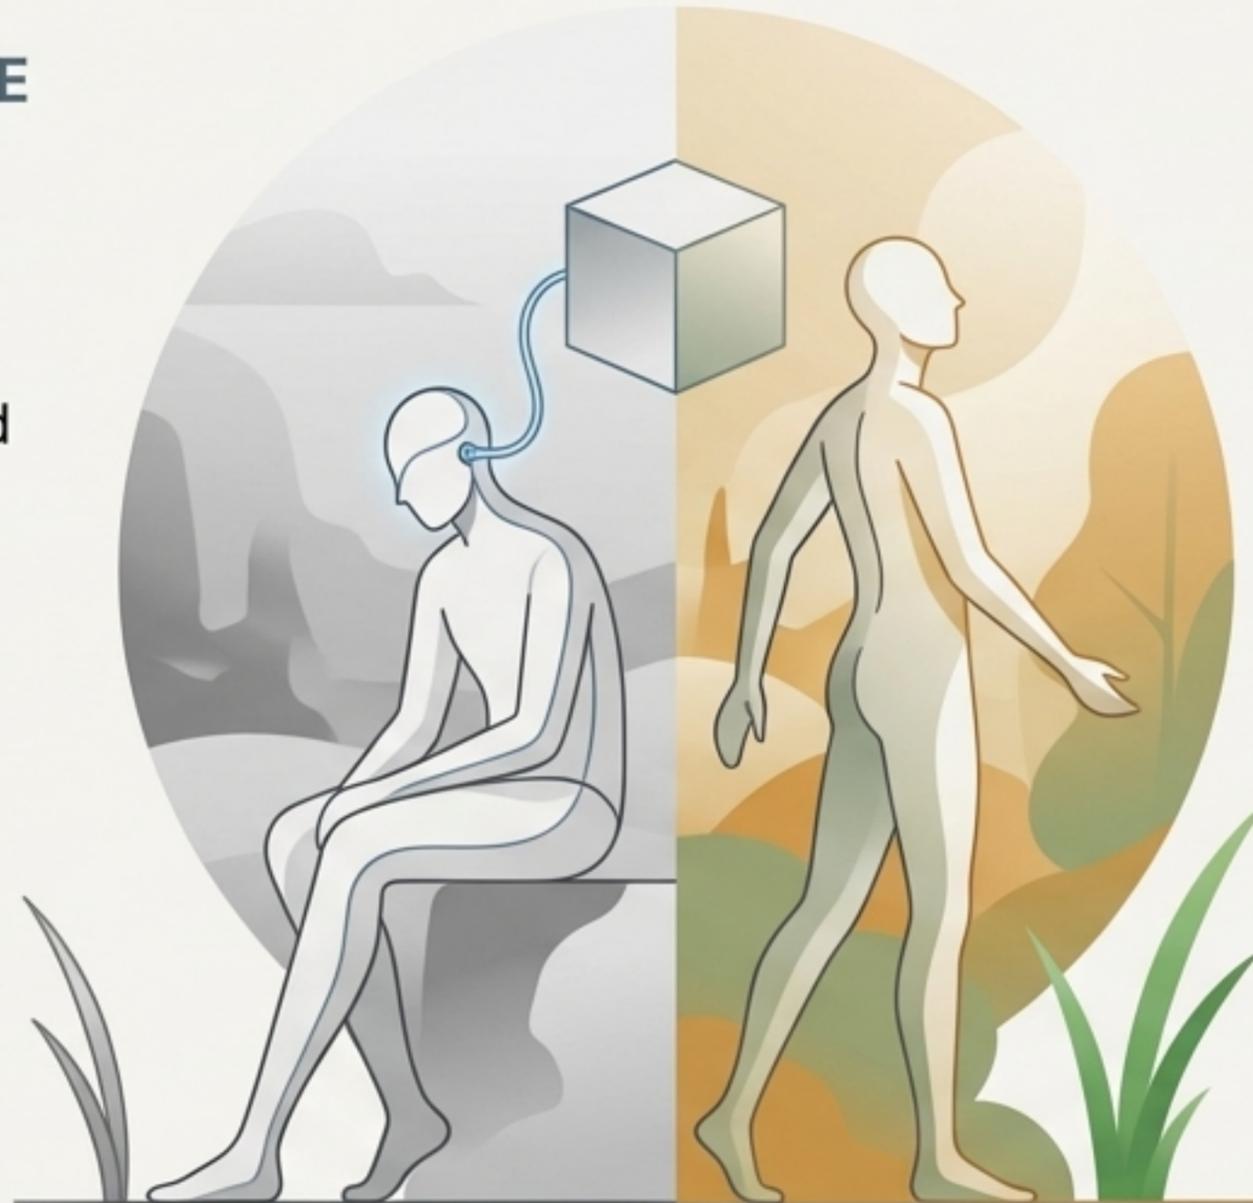

"Happiness" is a crude label, but computational neuroscience can identify its molecular signatures (receptor-density, gene expression). We can 're-encephalise' our emotions to benefit ourselves, not just our genes. This involves selectively overexpressing the neural correlates of well-being, such as by multiplying *mu*-opioid receptors, in a controlled and insightful manner.

## The Challenge

### 3. THE EXPERIENCE MACHINE

Isn't this just a sophisticated version of Nozick's Experience Machine?

We value real-world truths and authentic engagement, not simulated "false happiness", no matter how wonderful it feels.

## A Possible Path Forward

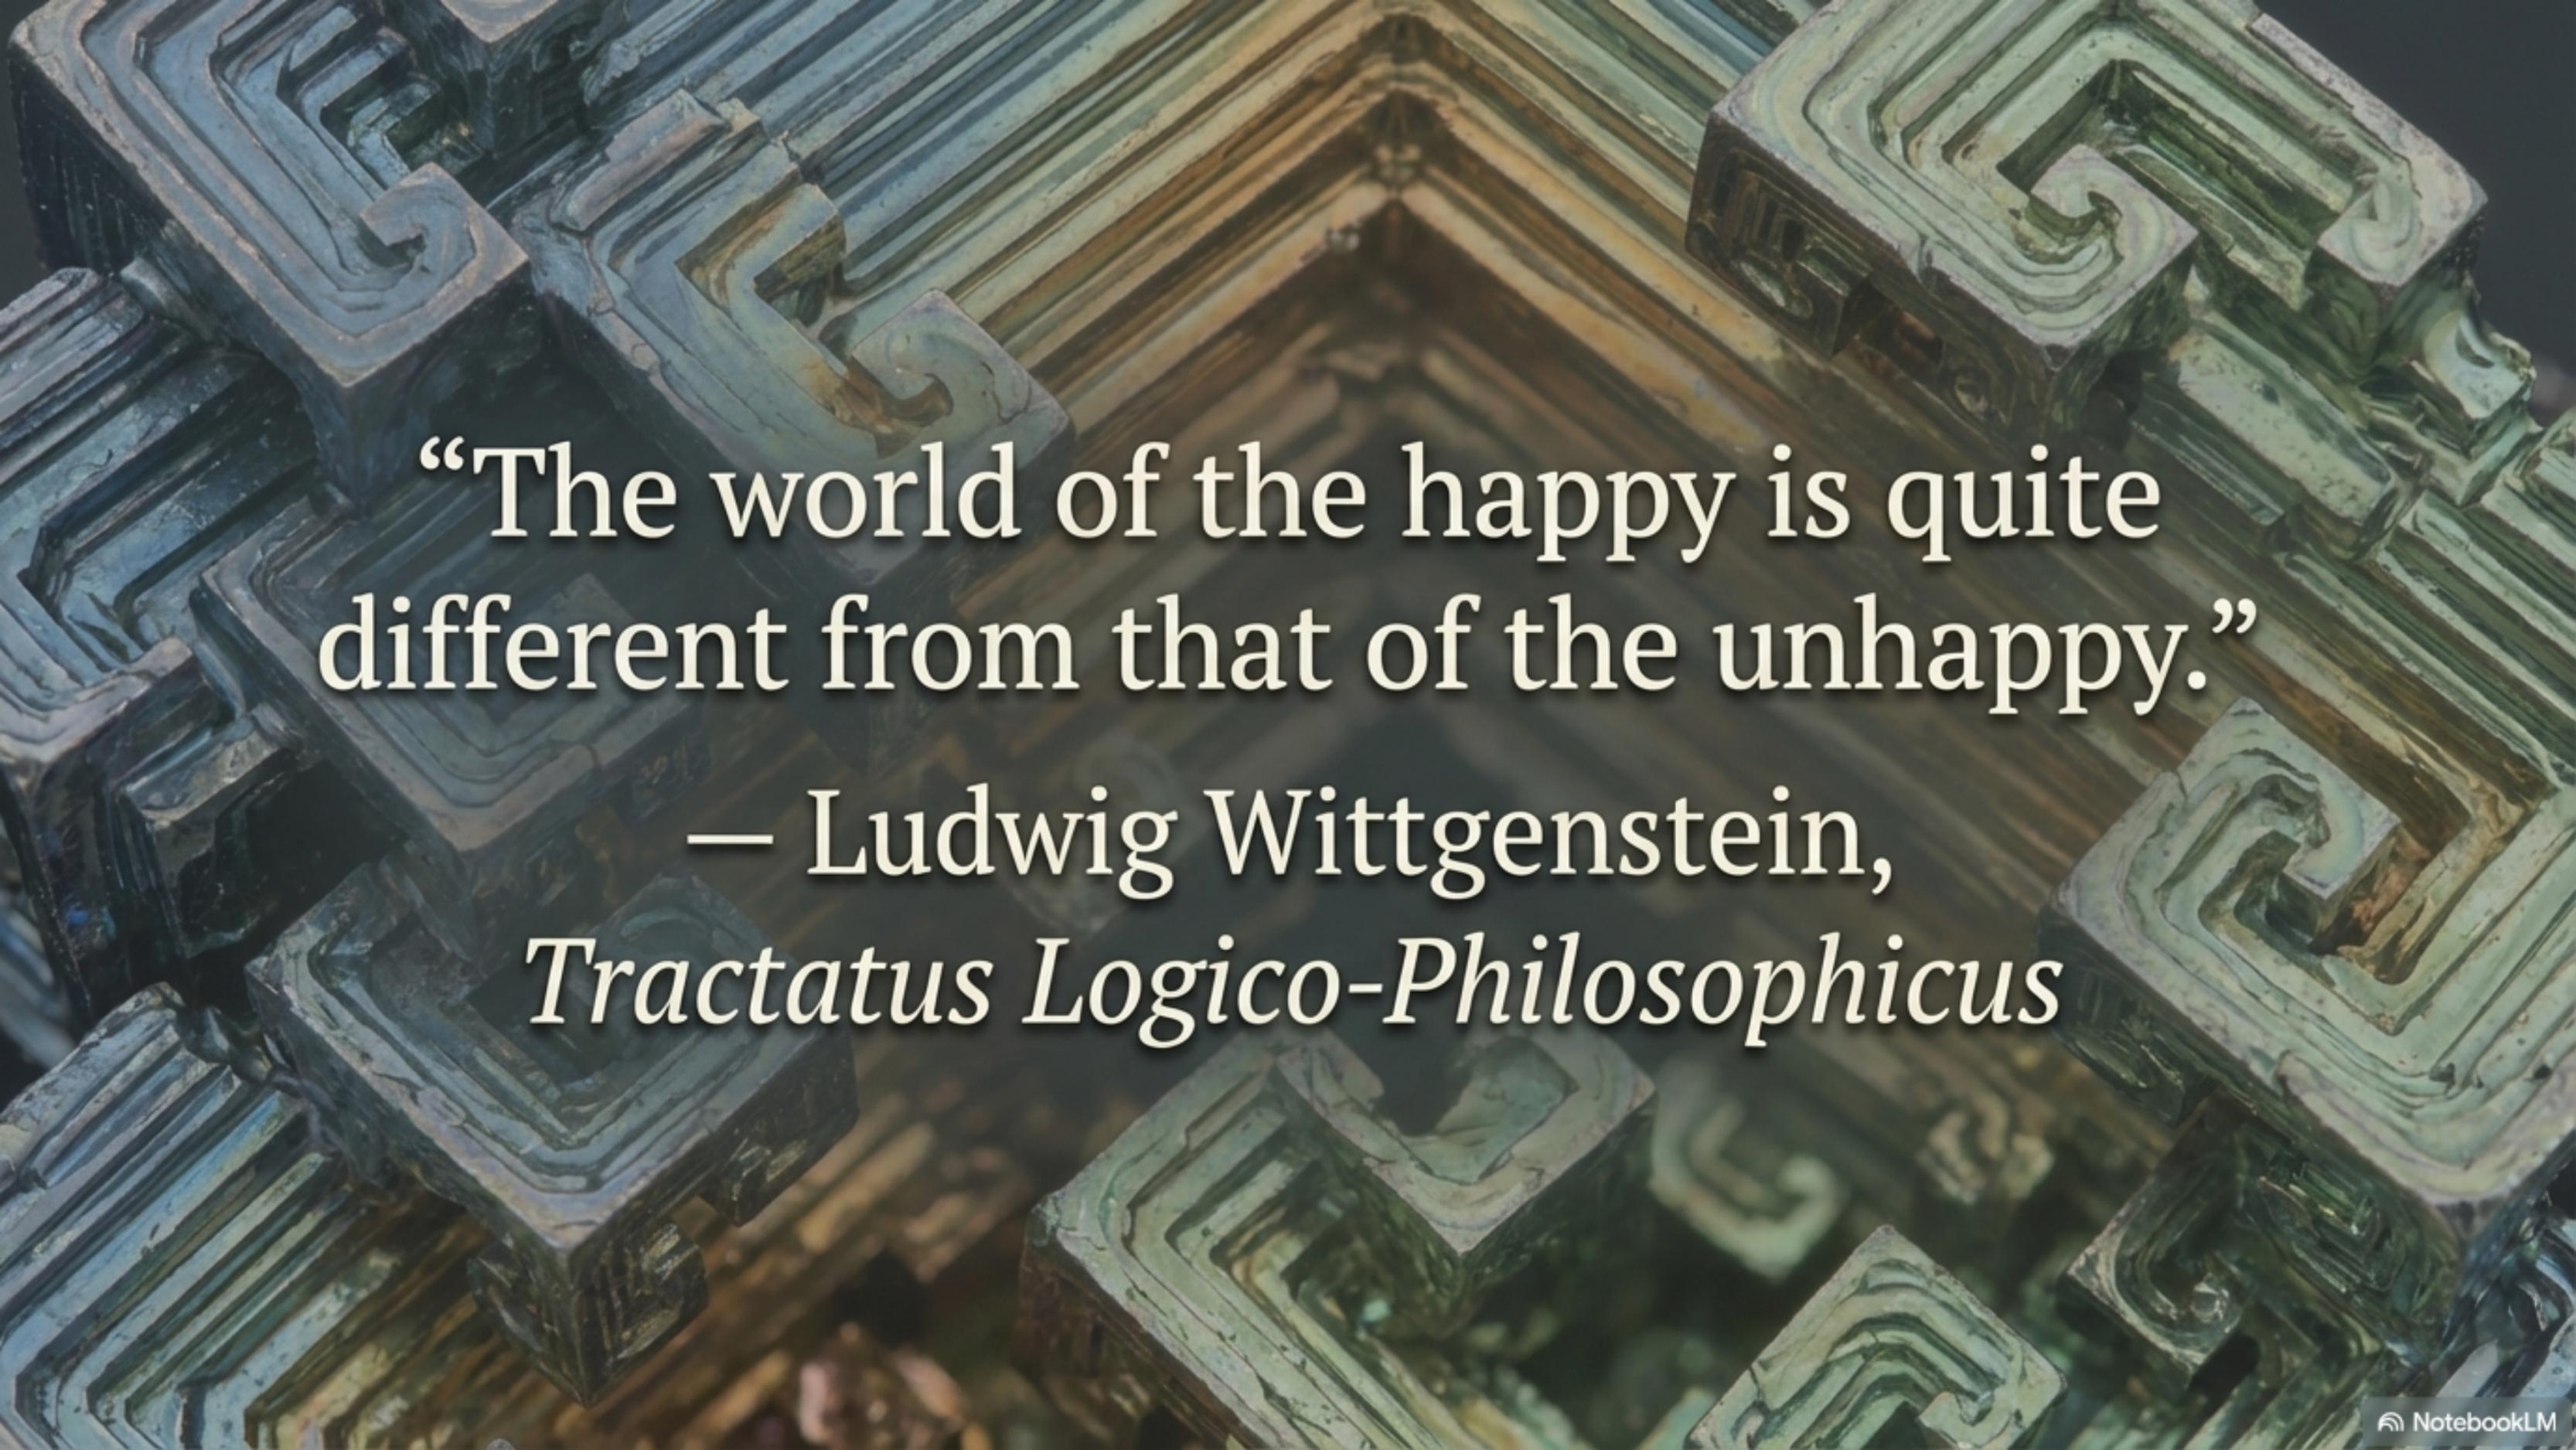

### RESPONSE

This is not about escapism. Genetically recalibrating our hedonic set-point aims to enhance engagement *with* the world—the opposite of clinical depression, which causes withdrawal.

Furthermore, our brains are already "dysfunctional experience machines" that subjective realities lives like dreams and the phenomenal experience of colour.

If a person born colourblind could receive gene therapy to see green, we wouldn't call that vision "fake".

Gradients of well-being are no less genuine than the greenness of grass.

“The world of the happy is quite different from that of the unhappy.”

— Ludwig Wittgenstein,  
*Tractatus Logico-Philosophicus*

# Part 2: The Impact on the Self

## The Challenges

### 4. INAPPROPRIATE RESPONSES

Would we lose critical negative feedback? Would your friends remain happy upon hearing of your tragic death? Our sense of appropriateness is vital.

### 5. CHARACTER-SAPPING

Will engineered well-being promote selfishness, egotism, and impaired judgment, like wireheading or drug addiction? Will it rob us of character-building struggles?

### 6. STUCK-IN-A-RUT

Could we become trapped in a suboptimal "fool's paradise", like Huxley's soma, preventing us from reaching our full potential?

## Possible Paths Forward

### RESPONSE (Responses)

Hedonic contrast can be preserved. The functional analogues of negative feelings can exist without the raw texture of suffering. One wouldn't want friends to suffer on one's account, but a reduction in their well-being is the most one could appropriately ask.

### RESPONSE (Character)

True hedonic engineering can be profoundly good for character. We can make altruism, kindness, and deep study more rewarding than they are today, overcoming the limitations of Darwinian biology. Mental superhealth promises stronger willpower, not weakness.

### RESPONSE (Stagnation)

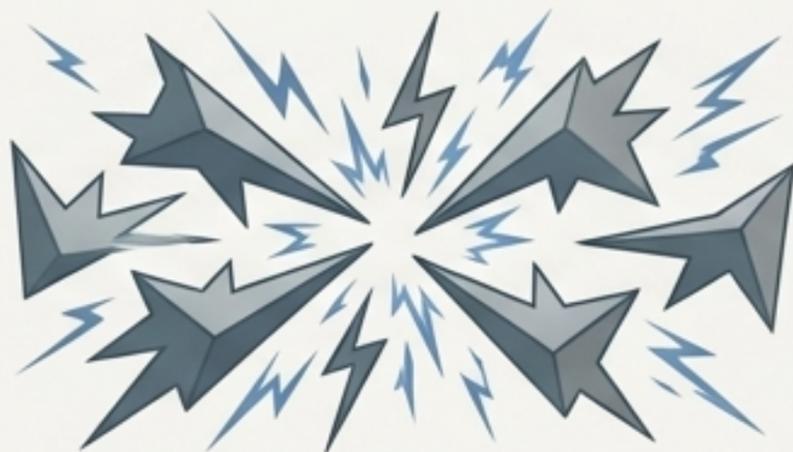

A credible risk that demands strategic foresight. Promoting "dopaminergically-enhanced" well-being (which drives novelty-seeking and curiosity) over purely contemplative or serene states could prevent civilizational stasis.

# Part 3: The Impact on Society & The Species

## The Challenges

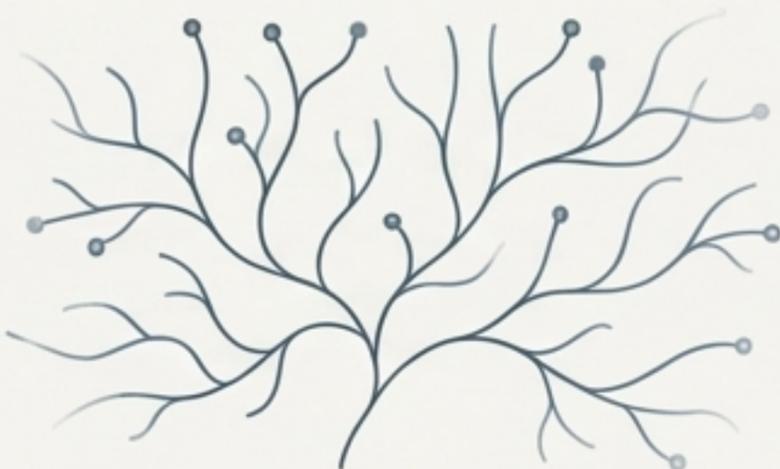

### 7. SOCIALLY DISRUPTIVE

If we abolish the biology of subordination (low mood, social anxiety), will we turn everyone into "alpha" personalities, making society ungovernable and hyper-competitive?

### 8. SELECTION PRESSURE

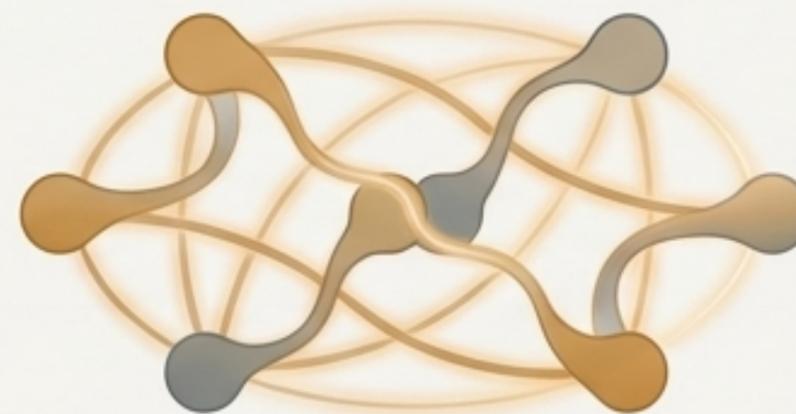

In the long run, won't natural selection work against escalating gradients of superhappiness? Wireheads, for instance, are not at a reproductive advantage.

## Possible Paths Forward

### 7. RESPONSE (Social Disruption)

This is a serious threat, highlighting the need for careful planning. However, mood-enrichment can also be pro-social. We can amplify mirror neurons or develop safe, sustainable genetic analogues of "hug-drugs" like MDMA to enhance empathy and social cohesion.

### 8. RESPONSE (Selection Pressure)

We are entering a post-Darwinian era of 'unnatural selection.' Through technologies like preimplantation genetic screening, parents will actively choose genotypes predisposing to well-being. This creates intense selection pressure for happier traits, a fundamental shift from blind evolution.

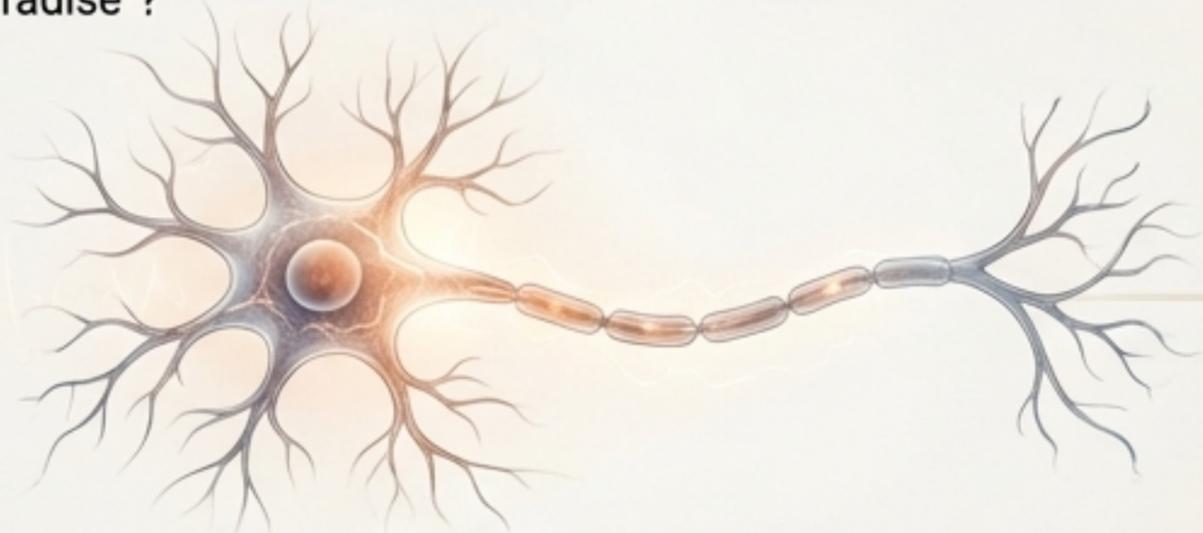

# Part 3: The Impact on Society & The Species

## The Challenges

### 9. RISKS OF HASTE

Shouldn't we prioritize developing superintelligence *first*, so we can fully understand the implications before we risk building a "fool's paradise"?

### 10. CARBON CHAUVINISM

Why focus on messy "biological substrates"? Why not scan and upload our minds to silicon, where we can reprogram ourselves for superintelligence and superhappiness with exponential speed?

## Possible Paths Forward

### RESPONSE (Risks of Haste)

This objection may be correct. However, emotional enrichment and empathetic understanding are critical *ingredients* of mature superintelligence, not a separate goal. We must combine extraordinary urgency (to end suffering) with extraordinary skepticism, recalling historical errors like Freud's early praise for cocaine.

### RESPONSE (Carbon Chauvinism)

Uploading poses an immense existential risk. We lack a scientific theory of consciousness and cannot scan or digitize qualia—the "what it feels like" of experience. Without this, we risk creating zombies. To proceed is to place faith in a metaphysical theory. For now, it is science-fantasy.

# A New Horizon for Well-being

The challenges are not insurmountable. Fine-grained control of our emotions is not a prescription for *how* to live, but an enabling technology to realize our projects more effectively and savor the outcome more appreciatively. The world of the superhappy is quite different from the human world. Whether we will ever investigate its properties is an open question, but the journey to enrich consciousness may be the most important exploration humanity can undertake.
